

Description

POLYMERIC COMPOSITE SEPARATION MEMBRANE

Technical Field

- [1] The present invention relates to a polymeric composite separation membrane and its preparation method. The separation membrane of the present invention which is produced by blending an amorphous thermoplastic resin, a semi-crystalline polymer and a compatibilizer which controls the dispersion state of the semi-crystalline polymer in the thermoplastic resin and adhesion at the interface, and then by preparation of a thin film of the blended mixture which is capable of increasing a selective permeation rate in such a manner that the dispersed semi-crystalline polymer is morphologically altered to serve as an obstacle to permeation, by which the permeation distance of the chemicals (liquid or gases) is extended. When applied to a gas separation process, this enhances the selective permeability over the so-called trade-off limit. More particularly, a semi-crystalline polymer which is hardly permeable to a gas or chemicals is dispersed in an amorphous thermoplastic resin, and at this time, an appropriate amount of compatibilizer is added so as for the semi-crystalline polymer to have a uniform size and well dispersed state, and then, the mixture obtained from the extruder is passed through a die as a thin film, whereby, the semi-crystalline polymer phase evenly dispersed and morphologically controlled in the film works as an obstacle to diffusion of chemicals or gases, to thereby morphologically altering path length of permeants. The chemicals or gases are separated according to interaction difference between the compatibilizer and permeant molecules, which induces diffusion time difference during which they pass the deformed path by the diffusion constant difference depending on the size of the chemicals or gas molecule and the interaction with the compatibilizer, thereby exhibiting a highly superior selectivity.

Background Art

- [2] Polymeric separation membranes are used for various separation processes which are technologically important such as liquids separation, drug delivery, drug release, artificial kidney and lung, separation of air, separation of carbon dioxide from a natural gas, or separation of nitrogen and oxygen or separation of hydrocarbon and hydrogen in a petrochemical process.
- [3] In the gas separation process, the basic factors determining the separation performance of polymeric gas separation membranes for a pair of gases (i.e., oxygen/nitrogen, carbon dioxide/methane or hydrogen/nitrogen, etc.) are permeability constant and selectivity. Permeability constant is typically obtained by dividing the multiplied

value of a gas concentration difference and the thickness of separation membrane by a pressure difference of both sides of the separation membrane. Selectivity is a ratio of permeability of two gases. That is, when the selectivity ratio is represented by A/B , 'A' is the permeability of high permeable gas and 'B' is the permeability of low permeable gas.

- [4] High performance separation membranes are desired to have a high permeability and a high selectivity, because a high permeability allows to reduce an area of separation membranes required for separating a certain amount of gas or chemicals and a high selectivity allows to enhance the purity of a product.
- [5] However, generally, if the separation membranes have a high permeability, it has a low selectivity, whereas if a separation membrane has a high selectivity, it has a low permeability.
- [6] According to Robeson's observation, as to separation of several pairs of gases, most polymer separation membranes have a negative slope in the correlation between the selectivity and the permeability (Journal of Membrane Science, Vol. 62, 165, 1991, USA). That means the selectivity is reduced as the permeability is increased.
- [7] In addition, upon observation of performance of numerous polymer separation membranes, it has been revealed that most of the polymer separation membranes do not exhibit a performance higher than a certain level. That is, for each permeability, there exists an upper limit of the selectivity, along which an inversely proportional relation exists between the selectivity and the permeability all the time. The reason why such an upper limit exists is a natural result as the hard chains of a glass phase polymer substance screen the gas molecules. The slope of the upper limit has no relation to a chemical structure of the polymer separation membranes.
- [8] For the past 30 years, in order to simultaneously increase the selectivity and the permeability, most researchers in the separation membrane industrial field have exerted their energy on synthesizing novel polymers (for example, US Patent No. 5,725,633). However, though many researches have been conducted, there has been no report on polymeric gas-separation membranes having a performance exceeding the existing upper limit. Very recently, we could make a polymeric- composite gas-separation membrane that has a selectivity going over the upper limit(U.S. Patent 6,517,606B2). In that case, the permeability of the prepared composite membrane was rather low to be practically used for the gas separation process, though.
- [9] The present invention is directed to a fabrication process of a polymeric gas (or chemicals) separation membrane that can overcome the upper limit on the basis of a novel concept of a polymer composite instead of synthesizing a new polymeric material. Prepared membrane has the permeability high enough to be applied for real processes.

Disclosure of Invention

Technical Problem

- [10] Therefore, an object of the present invention is to provide a process for fabricating a blend allowing a uniform dispersion and having an improved interface adhesion by adding a semi-crystalline polymer to an amorphous thermoplastic resin and at the same time, adding a compatibilizer so that the compatibilizer works at the interface of the semi-crystalline polymer and the thermoplastic resin to lower the interfacial tension, to provide a process for fabricating membranes with a desired thickness by performing extrusion and drawing, and to produce polymeric gas- or chemical separation membranes exhibiting a high selectivity in such a manner that almost impermeable semi-crystalline polymer uniformly dispersed in the film is formed in a thin and long plate type, working as an obstacle to a chemical or gas permeation to change a curvature for a diffusing molecules so that they pass through the channel at the interface where the compatibilizer is located and the mixed molecules are separated because of the interaction difference with the compatibilizer.
- [11] Another object of the present invention is to optimize dispersion of a semi-crystalline polymer by using an optimum amount of the compatibilizer.
- [12] Still another object of the present invention is to utilize a drawing process, for fabricating thin film membranes to let the dispersed phase have a different axial ratio.
- [13] Yet another object of the present invention is to provide a method for fabricating a semi-crystalline polymer blended high-selective gas separation membranes.
- [14] Still yet another object of the present invention is to provide a method for separating a gas or chemicals in liquid state by using the semi-crystalline polymer blended high selective separation membranes. For liquids separation process, the liquids do not dissolve the membrane or its components.

Technical Solution

- [15] To achieve these and other advantages and in accordance with the purpose of the present invention, as embodied and broadly described herein, there is provided a semi-crystalline polymer blended gas separation membrane obtained by melting and processing a 50~99 wt % of thermoplastic resin, 0.9~50 wt % a semi-crystalline polymer and 0.1~10 wt % of compatibilizer for the semi-crystalline polymer and the amorphous (or very low crystalline) matrix polymer.
- [16] To achieve the above objects, the method for fabricating semi-crystalline polymer blended separation membranes is provided, including the steps of : mixing a 50~99 wt % of thermoplastic resin, 0.9~50 wt % semi-crystalline polymer and 0.1~10 wt % of compatibilizer; and injecting the resulting mixture in an extrusion die and extend coming out film to fabricate an axially oriented film.

- [17] The foregoing and other objects, features, aspects and advantages of the present invention will become more apparent from the following detailed description of the present invention when the accompanying drawings are taken into consideration.

Advantageous Effects

- [18] As will be described below, the thin semi-crystalline polymer blended gas separation membranes fabricated in accordance with the present invention have many advantages.
- [19] For example, first, it exhibits the high selectivity exceeding the limit value, which has been hardly overcome by the existing separation membranes. Also, the permeability is high enough to be used in practical gas separation process.
- [20] Secondly, as a separation membrane fabricating technique with a novel concept combining a physical method and a chemical method, since the whole process is performed in the extruder, it does not require a complicated process such as a solution casting method, a post-treatment process such as a solvent recovery and processing is not necessary, and it is also possible to make separation membranes in large scale.
- [21] Thirdly, since it can be used between every crystalline polymer and thermoplastic resin as long as a suitable compatibilizer is available, it can be used to separate gases having different permeation rate from mixtures. It can also be used to separate liquid chemicals as long as they do not dissolve the membrane components.

Brief Description of the Drawings

- [22] The accompanying drawings, which are included to provide a further understanding of the invention and constitute a part of this specification, illustrate embodiments of the invention and together with the description serve to explain the principles of the invention.
- [23] In the drawings:
- [24] Top row in Figure 1 includes photographs of a scanning electron microscope (SEM) of a section of a membrane generated in accordance with a preferred embodiment of the present invention, of which Figure 1A is a SEM figure of a membrane section generated by binary blend system of semi-crystalline polymer (nylon6, 20 wt%)/poly(2,6-dimethyl-1,4-phenylene oxide) (PPO); Figure 1B is a SEM figure of a membrane section generated by ternary blend system of a semi-crystalline polymer (nylon6,20 wt%)/PPO/compatibilizer (2 wt%); Figure 1C is a SEM figure of a membrane section generated by ternary blend system of a semi-crystalline polymer (nylon6, 20 wt%)/PPO/compatibilizer (6wt%); and Figure 1D is a SEM figure of a membrane section generated by ternary blend system of a semi-crystalline polymer (nylon6, 20 wt%)/PPO/compatibilizer (10wt%)
- [25] Bottom row in Figure 1 is a photograph of a transmission scanning electron

microscope (TEM) of a section of a membrane generated in accordance with a preferred embodiment of the present invention, of which Figure 1A is a TEM figure of a membrane section generated by binary blend of a semi-crystalline polymer(20 wt%)/PPO; Figure 1B is a TEM figure of a membrane section generated by ternary blend of a liquid crystalline polymer (20wt%)/ PPO/compatibilizer (2 wt%); Figure 1C is a TEM figure of a membrane section generated by a ternary blend of a liquid crystalline polymer (20wt%)/PPO/compatibilizer (6wt%); Figure 1D is a TEM figure of a membrane section generated by a ternary blend of a liquid crystalline polymer (20 wt%)/PPO/compatibilizer (10wt%)

- [26] Figure 2 shows the relationship of oxygen permeability and the N_2/O_2 selectivity of the membranes prepared by using the present invention method.

Best Mode for Carrying Out the Invention

- [27] Reference will now be made in detail to the preferred embodiments of the present invention, examples of which are illustrated in the accompanying drawings.
- [28] A semi-crystalline polymer blended high selective gas separation membrane of the present invention comprises a semi-crystalline polymer, an amorphous (or very low crystalline)thermoplastic resin and a compatibilizer.
- [29] In the present invention, the semi-crystalline polymer is used in the amount of 0.9~50 wt %, preferably 5~25 wt %. All polymers containing some parts of crystalline phase can be used for the present invention, but the one having a high portion of crystalline phase, low melting point (preferably lower than 300°C), a lower melt viscosity than that of the matrix polymer (amorphous resin) at the processing temperature and conditions is more preferable.
- [30] In the present invention, the amorphous thermoplastic resin is used in an amount of 50~99 wt %, and preferably, 75~95 wt % and it is preferred that it does not decompose at a process temperature not lower than the melting temperature of the semi-crystalline polymer. In this respect, a melt viscosity is preferred to be higher than that of the semi-crystalline polymer for better deformation of the dispersed phase, though not necessarily required. In the present invention, any commercial thermoplastic resin can be used. In this respect, according to a preferred embodiment of the present invention, poly(2,6-dimethyl-1,4-phenylene oxide) (PPO) (a product of G.E. of USA), provided a favorable result.
- [31] In the present invention, the compatibilizer is used in an amount of 0.1~10 wt %, preferably 0.1~5 wt %, and most preferably 1~2 wt %. The compatibilizer is positioned at the interface of the matrix resin and the semi-crystalline polymer, lowering the interfacial tension between the crystalline polymer and the matrix resin, improving dispersion, and strengthening the interfacial adhesion.

- [32] Especially, it is preferred not to be decomposed at a process temperature of the semi-crystalline polymer and the matrix resin, to be positioned at the interface of the dispersed phase to lower the interfacial tension and accordingly evenly disperse the dispersed phase, and to improve the adhesion at the interface.
- [33] A compatibilizer used in the present invention can be any compound giving compatibility to the matrix thermoplastic resin and the semi-crystalline polymer. For example, it can be a block copolymer, a graft polymer or a copolymer generated by interfacial reaction. According to the preferred embodiment of the present invention, as the compatibilizer, poly(styrene-co-maleic anhydride), provided a favorable result. It is well known that polystyrene forms a miscible blend with PPO and the amine end group of nylon 6 reacts with maleic anhydride. Thus the compatibilizer has a graft copolymer structure.
- [34] A process for preparing the semi-crystalline polymer blended high selective gas separation membrane includes the steps of: a) mixing 50~99 wt % of an amorphous thermoplastic resin, 0.9~50 wt % of a semi-crystalline polymer, and 0.1~10 wt % of compatibilizer based on the thermotropic liquid crystalline polymer; b) after passing through the extrusion die, the film was uni-(or bi-)axially drawn to produce an oriented composite film.
- [35] The semi-crystalline polymer blended in a high-selective gas-separation membrane produced by the present invention works as an obstacle against the gas permeation, so that the gas molecules should pass around the dispersed crystalline phase where the compatibilizer resides, and accordingly, the gas molecules interact with the compatibilizer, and the distance for the gas molecules to diffuse out is considerably increased.
- [36] The gas molecules are normally diffused through the path of a free volume of the amorphous thermoplastic resin. In this respect, the diffusion coefficient is different depending on the size of the gas molecules, and thus, the diffusion flux becomes different. As the distance along which the gas molecules pass is long, the diffusion flux between the gas molecules are differentiated, and due to the interaction with the compatibilizer, there is a difference in the distance that the gas molecules are diffused for the same time, resulting in a high selectivity.
- [37] In the preparation method of the present invention, the mixing step may be performed by a general method, such as by using a twin screw extruder, single screw extruder and an internal mixer.
- [38] The drawing step in the preparation method of the present invention is conducted in a tensile apparatus connected to the extrusion die. The drawing can be biaxial drawing using simultaneous extension or film blowing process, and the dispersed semi-crystalline phase has a stripe shape, of which a drawing ratio in the one axis direction

is higher than a drawing ratio in the other direction.

[39] When the film blowing process is applied, a dual mandrel of which outside and inside are rotated in the opposite direction may be used instead of the extrusion die so that the deformed semi-crystalline phase may be formed as a net shape. Or, a multilayer film composed of many layers may be fabricated by using a multilayer-co-extrusion die.

[40] The invention will be further illustrated by the following examples. It will be apparent to those having conventional knowledge in the field that these examples are presented only to explain the present invention more clearly, but the invention is not limited to the following examples.

Mode for the Invention

[41] As a semicrystalline polymer, a raw material, nylon 6 (Kolon 171, Korea) was used. As a matrix resin, poly(2,6-dimethyl-1,4-phenylene oxide) (PPO) (a product of G.E. of USA) was used. As a compatibilizer, a random copolymer between styrene and maleic anhydride, poly(styrene-co-maleic anhydride), containing 7wt% of maleic anhydride was used.

[42] After nylon 6, PPO and the compatibilizer were dried in a vacuum oven at a temperature of 100°C for more than 24 hours, they were premixed with the ratio in Table 1. The resulting mixture was then extruded at a process temperature of 240°C in a Bravender twin screw extruder. It is well known that polystyrene is miscible with PPO and amine group of nylon 6 reacts with maleic anhydride group very well. Thus while mixed and blended in the extruder, the random block copolymer reacts with nylon 6 to form a graft copolymer. This graft copolymer should be located at the interface due to enthalpic and entropic interaction with the matrix (PPO) and the dispersed phase (nylon 6). Polystyrene section of the compatibilizer would be in the matrix side while grafted polyamide parts reside in the dispersed nylon 6 phase. Thus, interfacial adhesion is enhanced while the interfacial tension between those two phases is significantly reduced.

[43] A flat die was connected to an exit of the twin screw extruder and the blend was subjected to an extension with a drawing unit. The extension ratio was adjusted with the rate of the winding speed to obtain a thin film of a uniform thickness. After then the film was wound. A film with an even thickness of 100 μ m having 3% error limit was used.

[44] After the film samples were installed in a testing container, and an absorption gas was discharged under a high vacuum (10^{-6} torr) before measuring a permeation rate. In the testing apparatus, an isometric method was used in which a pressure increase in the opposite side of a side where a pressure was not applied was measured. The related

process is described in detail in ASTM D1434-82.

[45] Experiment was performed for the separation of oxygen and nitrogen which are most difficult to separate among the gases. The reason for this is that kinetic diameters of oxygen molecule and nitrogen molecule are respectively 3.46 and 3.64Å having little difference each other. The feasibility of this mechanism can be confirmed by measuring the permeability of CO₂ (P_{CO₂}) and the selectivity of $\alpha_{\text{CO}_2/\text{N}_2}$. In the experiment, the upstream pressure was 1 atm and the temperature was maintained at 35°C.

[46] In order to compare the separation capability of the three-component blend film of the present invention and a simple film (a test sample 2) made under the same condition but by mixing only two components, i.e., PPO and semi-crystalline polymer (nylon 6) without using the compatibilizer, the respective permeability and selectivity of ternary blend film were also measured. The results are shown as follows in Table 1.

[47] Table 1

Permeabilities and selectivities at 35°C						
No.	Films	P _{O₂} (Barrer) ^(a)	P _{N₂} (Barrer)	P _{CO₂} (Barrer)	$\alpha(\text{P}_{\text{O}_2}/\text{P}_{\text{N}_2})$	$\alpha(\text{P}_{\text{CO}_2}/\text{P}_{\text{N}_2})$
1	PPO	16.8	4.1	61	4.4	14.4
2	PPO/NY(20%)	7.32	1.53	24.8	4.77	16.15
3	PPO/NY(20%) /PSMA(2%)	3.02	0.309	12.0	9.75	38.7
4	PPO/NY(20%) /PSMA(4%)	4.06	0.474	17.0	8.56	35.87
5	PPO/NY(20%) /PSMA(6%)	3.29	0.469	12.9	7.01	27.43
6	PPO/NY(20%) /PSMA(10%)	2.65	0.325	11.1	8.15	34.22

[48] (a) 1 Barrer=10⁻¹⁰ cm³(STP)cm/(cm²s cmHg)

[49] In case that a film is fabricated by adding the semi-crystalline polymer into PPO, though the permeation rate was a little bit reduced due to the addition of the crystalline phase having less free volume, its selectivity was increased.

[50] The results of ternary blend system depend on the amount of the compatibilizer.

[51] When 2 wt % of compatibilizer was added (test sample 3), as shown in Figure 1B, the semi-crystalline polymer (nylon 6) was uniformly and finely dispersed in the

matrix resin, PPO. Its size was remarkably reduced. Though the permeation rate was reduced, the selectivity was significantly increased. The selectivity at this time exhibits a higher value than a limit value of the existing separation membranes (See Figure 2).

[52] Meanwhile, in case that an excessive amount of compatibilizer was added (test sample 4 and 5), the selectivity was rather decreased. This difference results from the fact that, as shown in Figures 1B, in case that a suitable amount of compatibilizer is introduced, the size of the dispersion phase was rapidly reduced compared to the case of the binary system and was evenly dispersed, while, as shown in Figures 1C and 1D, if the compatibilizer is added in an excessive amount, it forms its own phase as well as surrounding the periphery of the dispersed phase, and accordingly, the dispersed phase is coagulated.

[53] In case of the three component blend (sample 3) showing the uniform dispersion, as aforementioned, the permeating gas molecules should pass the boundary portion of the impermeable semi-crystalline polymer, of which the distance is proportionate to the square root of the number of dispersed phase, being far more lengthened. The path around the semi-crystalline polymer is occupied by the compatibilizer, which interacts differently for different gas molecules (oxygen and nitrogen).

[54] Accordingly, the small difference of diffusion constant ends in a large difference of the permeation rate of oxygen and nitrogen while the gas molecules pass the long distance receiving different interactions from the compatibilizer, resulting in that oxygen comes easily, and thus, high permeation rate and selectivity of oxygen are obtained. This is similar to the separation principle of a gas chromatography.

[55] On the other hand, in case that an excessive amount of compatibilizer was introduced, the path length is reduced due to the coagulation of dispersed phase and the interaction with the compatibilizer also decreased, resulting in lowering of the selectivity. When excessive amount of the compatibilizer was added they form their own phase and the selectivity was increased slightly because the selectivity of the film made of solely compatibilizer for O_2/N_2 pair is relatively high.

[56] In the present invention, PPO was used as a matrix, mixed with a polyamide (nylon 6), to which a random block copolymer of styrene and maleic anhydride was added as the compatibilizer, thereby fabricating the extended film after die exit. In view of the morphology of the extended film, the dispersed phase and the interfacial adhesion were confirmed by the electronic microscopy. In addition, by separating oxygen and nitrogen, which are the most difficult to be separated as their molecular sizes are similar, the performance of the film was measured.

[57] The feasibility of this mechanism can be confirmed by measuring the permeability of CO_2 (P_{CO_2}) and the selectivity of α_{CO_2/N_2} . The results are shown in Table 1. The behavior of P_{CO_2} and P_{CO_2/N_2} vs P_{CO_2} follows exactly that of P_{O_2} and α_{O_2/N_2} . Addition of

the semi-crystalline Ny6 phase into PPO (binary blend film) decreases P_{CO_2} compared to that of PPO film whereas it increases the selectivity α_{O_2/N_2} a little bit. The selectivity of the ternary blend film containing 2wt% PSMA shows a remarkable increase. Though the permeability has been decreased a little bit, the selectivity increased more than twice of that of the binary blend film. Permeability of this film is high enough (12 Barrer) to be used for the removal of CO_2 . Addition of more compatibilizer leads to coalescence of dispersed Ny6 phase (Fig.1). Then, the selectivity α_{O_2/N_2} decreased while the permeability P_{CO_2} increased. Further addition of PSMA results in the formation of PSMA own phase. High selectivity of PSMA (α_{O_2/N_2} of PSMA is 34.64) and low permeability compared to that of PPO (P_{CO_2} of PSMA is 10.8) bring in lower P_{CO_2} and high α_{O_2/N_2} . After each passage through the compatibilizer around a dispersed phase, the concentration of CO_2 would go up and up and high selectivity is achieved. This result confirms the role of the compatibilizer acting as an organic molecular sieve for selection of gas molecules.

[58] As so far described, the thin semi-crystalline polymer blended gas separation membranes fabricated in accordance with the present invention have many advantages.

[59] For example, first, it exhibits the high selectivity exceeding the limit value, which has been hardly overcome by the existing separation membranes. Also, the permeability is high enough to be used in practical gas separation process.

[60] Secondly, as a separation membrane fabricating technique with a novel concept combining a physical method and a chemical method, since the whole process is performed in the extruder, it does not require a complicated process such as a solution casting method, a post-treatment process such as a solvent recovery and processing is not necessary, and it is also possible to make separation membranes in large scale.

[61] Thirdly, since it can be used between every crystalline polymer and thermoplastic resin as long as a suitable compatibilizer is available, it can be used to separate gases having different permeation rate from mixtures. It can also be used to separate liquid chemicals as long as they do not dissolve the membrane components.

[62] Through the present inventors used a single extruder for a monolayer film, it can be extended to multiple layer extruder. Also it can be easily modified to have a film-blowing die after extruder to produce a blown film. Also a pair of counter rotating mandrels for the extrusion die in the film blowing process can be adopted, hence to produce a membrane in which the dispersed crystalline phases are declined to 45° with each other (inside and outside).

[63] As the present invention may be embodied in several forms without departing from the spirit or essential characteristics thereof, it should also be understood that the above-described embodiments are not limited by any of the details of the foregoing description, unless otherwise specified, but rather should be construed broadly within its

spirit and scope as defined in the appended claims, and therefore all changes and modifications that fall within the metes and bounds of the claims, or equivalence of such metes and bounds are therefore intended to be embraced by the appended claims.

Industrial Applicability

[64] Here we applied the idea of present invention to prepare a polymer composite film for the gas separation. However, it can be easily applied to any membranes used in the chemical mixture separation process such as reverse osmosis, drug delivery, drug release, artificial kidney, and artificial lung to name a few as well as liquids separations. Thus any separation process using the composite polymer film of this invention should also be embraced by the appended claims.
